

Please note that Power Input and Output nets to ICs and connectors are not explicitly labeled, as the power labels (5V, VDC, etc) have higher priority over the regular labels and thus show up on the layout over the regular labels.
PWR_FLAGS are used to denote power input or outputs to KiCAD.

Power Sequence: Barrel jack or Battery --> Turns on 5V_AO --> 5V_AO powers Power Logic, which feeds high to 5V Buck Enable --> 5V PGOOD turns on Jetson Nano module --> SYS_RST turns on 3V3 buck --> 3V3 buck turns on 1V8 LDO

Thermistor to be attached to
the battery via adhesive
and connected to the circuit.
Thermistor header should
be soldered on by user.

Battery Charger Notes
Fsw = 600kHz

Max Ratings
Vin = 15–20V
Vsw = −0.3V to Vin + 0.3V
Vbs = Vsw + 6V
Vcsp, Vbatt = −0.3V to 18V
Vref33 =3V3
All other pins = −0.3V to 6V

Inductor (L2) must be able to handle 1.725A and have
DCR < 200mΩ.
D1 must be able to handle the inductor current

Voltage ratings and some of the component values were chosen
based off of reference schematic provided by
Monolithic Power Systems

Battery charger and buck converter calculations to determine parameters for
inductors and output voltages can be found in the github repository.

Sheet: /Power_1/
File: Power_1.sch

**Title: Jetbot Mini A01 Schematic**

| Size: A4 | Date: | Rev: A01 |
|---|---|---|
| KiCad E.D.A. kicad (5.1.10)-1 | | Id: 6/10 |

This part of the schematic was adapted from Jetson Nano Devkit baseboard B01 sku (https://developer.nvidia.com/embedded/downloads, schematic listed as "Jetson Nano Developer Kit Carrier Board Design Files (P3449 B01)").

PWR_FLAG tells KiCAD that the net is a power input. Used for DRC purposes.

Designed for use with MakerFocus I2C OLED Display, which has an onboard LDO that accepts Vin = 1 – 6 V and Vout = 3.3 V. Use 5V as 3V3 would yield a small voltage drop in the output.

Use I2C1_SCL and I2C1_SDA for compatibility with Jetbot SD Card Image

Use two 0 ohm resistors, one pulled up to 5V and one pulled up to 3V3, NS one of them, to be able to choose what voltage rail to connect the OLED display to.

Note that J13 is NS as user should solder on male headers.

MOD_SLEEP pin controls standby on motor controller, with VCC = 3.3V, V_IH (min) for standay pin is 2.31V, therefore needs level shifter.

SYS_RST controls 3V3 buck enable and USB power switch enable, which have V_IH (typ) = 2.5V and V_IH (min) = 1.5V respectively. AP6503 has V_EN ratings from −0.3 to 6V, and RT9742 has V_EN ratings from −0.3V to 7V

Cannot use regular level shifter as 3V3 rail will not be on without SYS_RST enable signal

Recommended operating conditions for 74LVC4245A state VCCA > VCCB, hence the flipped orientation.

MOSFET with large Vgs tolerance needed as input voltage from barrel jack is being fed into these pins.

EEPROM is to store information about the baseboard, for example if remoting into the board you can check the EEPROM and determine information about the board. For example, A00 vs A01 iteration might have differences that software needs to know about, like GPIO defn, etc.

R50 to hold Enable low until VCCA and VCCB are ready

1x6 0.1" Male Pins Debug Header Designed to work with FTDI Friend Connector NS so user can solder on male headers

3.3V Buck Converter Notes
f = 340 kHz
Vbst = Vsw−0.3 – Vsw+0.6
Vcomp = −0.3V – 6V
C39: Must be min 22uF, ESR = 0.64Ω for Vripple = 0.1V.
Value recommended by Datasheet
C27 and C39 for EMI/EMC
Output Inductor (L1) must have resistance of <300mΩ
Most of the component values were chosen by
the suggested values for outputting 3.3V using
Vfb = 0.925V
R1 = R2 * ((Vout / 0.925V) – 1)
R1 = 10k * ((3.3V / 0.925V) −1)
R1 = 25.676k
Two closest resistor options are 25.5k and 26.1k on LCSC:
Vout = Vin * (10k) / (10k + 26.1)
Vin = 0.925 * (10k + 26.1k) / (10k) = 3.33925V
Vin = 0.925 * (10k + 25.5k) / (10k) = 3.28375V
Better to use 26.1k.
Output Voltage Tolerance range w/ 26.1k: 3.291V – 3.388V

Designed so "low battery" means approximately 20% of charge left. Choice of 20% charge due to comparison with phone case, where around 20% battery is when the phone prompts user to charge. Used the following website: https://blog.ampow.com/lipo-voltage-chart/ as a reference for voltage vs SOC curve for LiPo batteries. Note that 11.18V corresponds with 20% charge, but due to potentially different LiPo batteries having different curves, a more conservative estimate of 11.24V or 25% charge was used for the lower voltage for the hysteresis. The voltage high threshold was chosen to be around 50% charge, or 11.51V, to bring the value of the hysteresis resistor (in this case R63) to a "reasonable" value.

Thus the operation of the hysteresis should proceed as follows: R44 and R45 resistor divider brings the voltage down so that it can be compared on a 5V scale. Initially "COMPARATOR_V−" net should be greater than "COMPARATOR_V+" net, so output is pulled low and "COMPARATOR_V+" net should be at the lower threshold voltage, in this case about 1.42V (which corresponds to 11.24V via the R44 and R45 divider). When "COMPARATOR_V−" net dips below this lower threshold voltage, output of the comparator is pulled high via R43 turning on the LED and "COMPARATOR_V+" is set to the higher threshold voltage, in this case about 1.45V (which corresponds to 11.51V via R44 and R45 divider). Thus the battery voltage on the "COMPARATOR_V−" must rise above 11.51V for the low power LED to turn off.

PLEASE NOTE that this hysteresis circuit is WIP, as R63 is a huge resistor value. Also note that Rh, in this case R63, should be at least 100 * R_pullup, in this case R43, to avoid R43 messing with the hysteresis threshold voltages. | KiCad E.D.A. kicad (5.1.10)−1 | | Id: 9/10 |

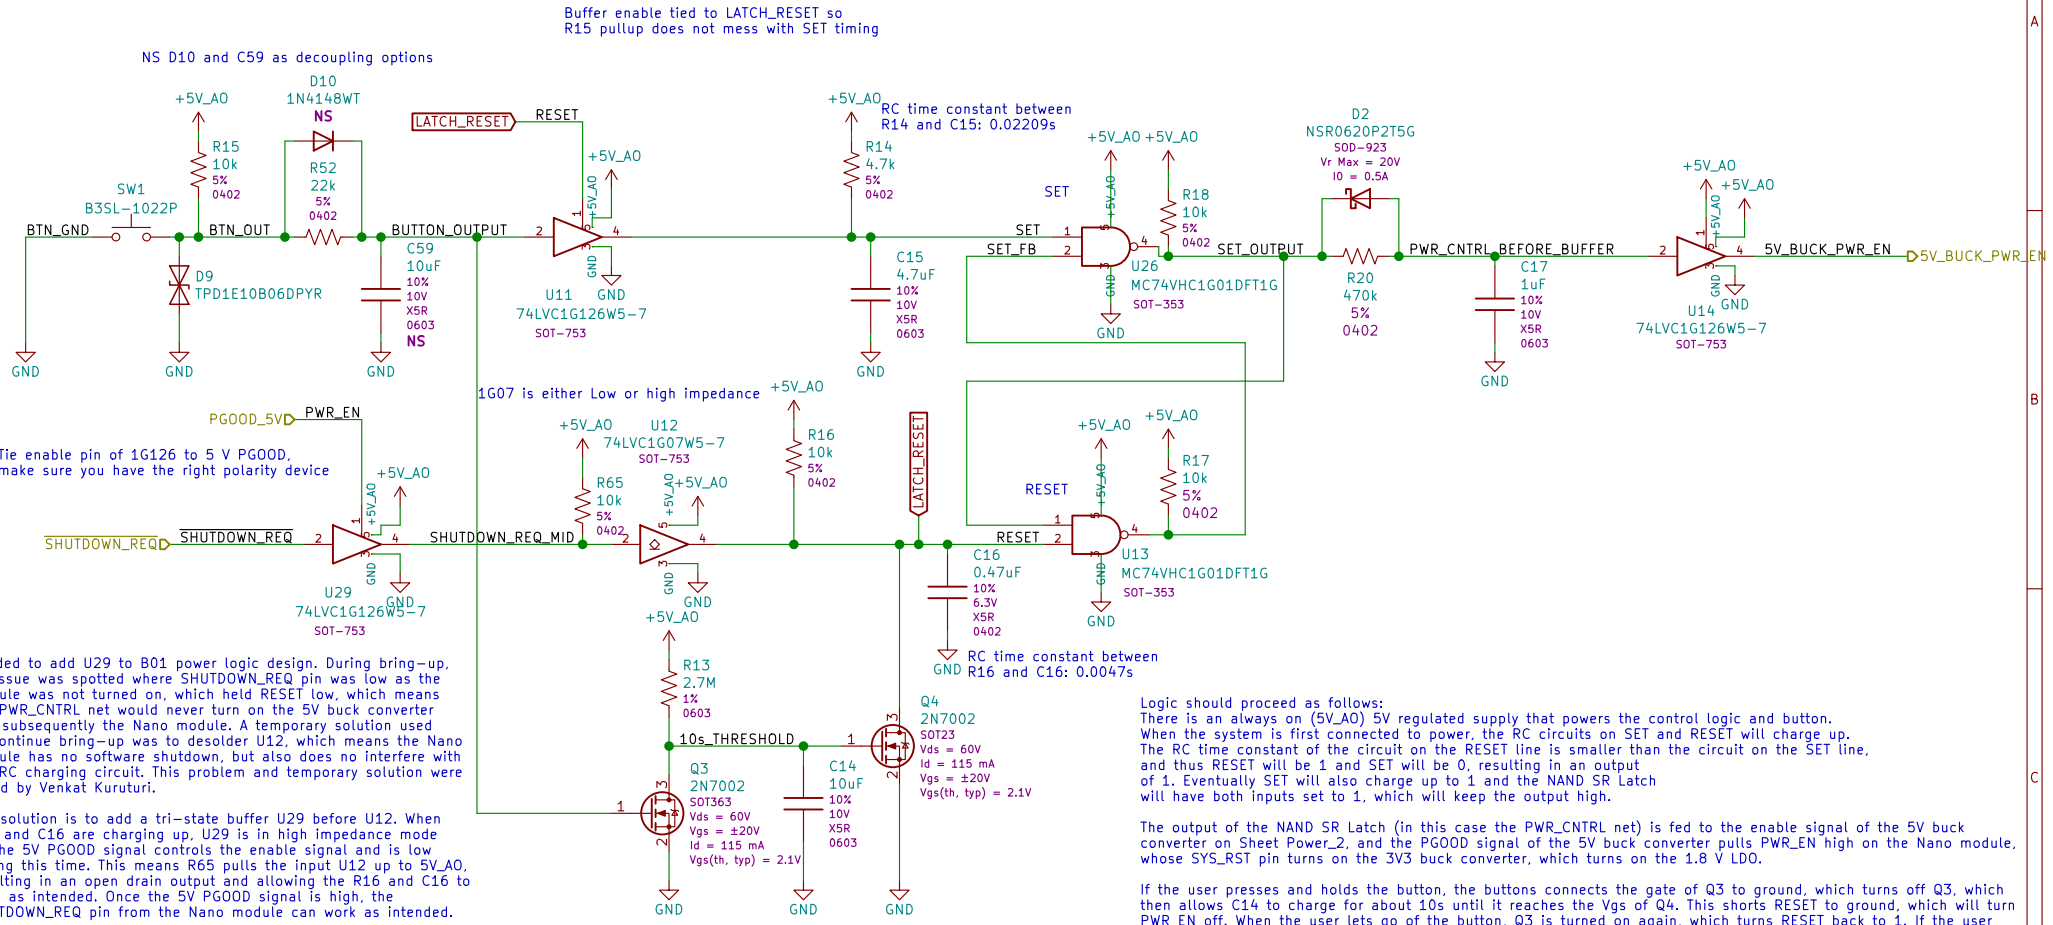
This part of the schematic was adapted from Jetson Nano Devkit baseboard B01 sku
(https://developer.nvidia.com/embedded/downloads, schematic listed as
"Jetson Nano Developer Kit Carrier Board Design Files (P3449 B01)").



Needed to add U29 to B01 power logic design. During bring-up, an issue was spotted where SHUTDOWN_REQ pin was low as the module was not turned on, which held RESET low, which means the PWR_CNTRL net would never turn on the 5V buck converter and subsequently the Nano module. A temporary solution used to continue bring-up was to desolder U12, which means the Nano module has no software shutdown, but also does no interfere with the RC charging circuit. This problem and temporary solution were found by Venkat Kuruturi.

The solution is to add a tri-state buffer U29 before U12. When R16 and C16 are charging up, U29 is in high impedance mode as the 5V PGOOD signal controls the enable signal and is low during this time. This means R65 pulls the input U12 up to 5V_AO, resulting in an open drain output and allowing the R16 and C16 to work as intended. Once the 5V PGOOD signal is high, the SHUTDOWN_REQ pin from the Nano module can work as intended.

Logic should proceed as follows:
There is an always on (5V_AO) 5V regulated supply that powers the control logic and button.
When the system is first connected to power, the RC circuits on SET and RESET will charge up.
The RC time constant of the circuit on the RESET line is smaller than the circuit on the SET line,
and thus RESET will be 1 and SET will be 0, resulting in an output
of 1. Eventually SET will also charge up to 1 and the NAND SR Latch
will have both inputs set to 1, which will keep the output high.

The output of the NAND SR Latch (in this case the PWR_CNTRL net) is fed to the enable signal of the 5V buck converter on Sheet Power_2, and the PGOOD signal of the 5V buck converter pulls PWR_EN high on the Nano module, whose SYS_RST pin turns on the 3V3 buck converter, which turns on the 1.8 V LDO.

If the user presses and holds the button, the buttons connects the gate of Q3 to ground, which turns off Q3, which then allows C14 to charge for about 10s until it reaches the Vgs of Q4. This shorts RESET to ground, which will turn PWR_EN off. When the user lets go of the button, Q3 is turned on again, which turns RESET back to 1. If the user wants to turn the system back on, the user must press the button once, which will short SET to 0, which turns the system back on.

Note that the circuit should auto power on the Jetson Nano module and that SET and RESET are both active low.
